## ABSTRACT

The purpose of this study is to determine the main potential risks that occur in the design planning stage of a construction project, especially in an Industrial Building project. Based on the available literature and the experiences of other authors and practitioners, a list of potential risks was developed. Risks events were initially categorized into technical, project management, commercial and external categories. Risks are evaluated by professional practitioners who have experience in construction projects. The evaluation includes the expected likelihood of the event and its impact on changes in scope of work. This study considers each risk among owners, consultants, contractors and others. The data collected were analyzed qualitatively and quantitatively to assess the severity and impact of the event. The recommended responses to major risks are introduced in this study.

**Keywords:** risk management model, planning stage, industrial building

## INTRODUCTION

Risk assessments are necessary to anticipate and prevent accidents from occurring or repeating (Lough, K. G. et al., 2007). Risk event from a different project is different from the risk event on another project. Likewise, the level of occurrence and impact in each project is always changing from one project to another. This makes it difficult for management to handle risks on new projects. Lack of risk management, even inadequate risk analysis,

can put construction projects in jeopardy (Basari, I., 2017). According to research by (Awuni, M.A., 2019) revealed that from the 114 consultants only had minimal knowledge about the implementation of risk management at the planning stage. Many respondents know the theoretical knowledge of risk management and its application at the planning stage. There are also many studies that examine risk management at the construction stage or development stage. However, there are rarely studies that discuss risk management at the planning stage. Whereas at this stage most of the major decisions are made which will later affect the success of a construction project. Therefore, this research is very important in order to know the negative impact due to the lack of implementation of risk management at the planning stage.

Construction Project is a process where activity includes different risks that must be handled by all project actors. The planning stage is the initial part of a development project where the project solution is selected from a variety of competitive alternatives that meet the project requirements. This is the stage where the risks associated with a decision can have an impact on the success of a project. In order to minimize the negative consequences of decisions made during the planning stage and to achieve the benefits of the actions taken, appropriate risk management should be used from the early stages of a development project. However, it

is common nowadays that the risks in the decision making stage are not considered by project actors in depth, because the capabilities in risk identification, risk assessment and risk management have not been fully developed. Most of the knowledge and experiences of project actors are used in the realization of project development but are rarely associated with risks in decision making or planning. New development projects are not always considered unique and their routines and work schemes accumulate from previous projects without considering the risk and the need for innovation to make the final solution more specific and competitive. Each stage requires good decisions to take further steps towards project success. The negative consequences of decision making will impact several stages of the project. Therefore, risk management is a very important thing to do in a construction project.

## LITERATURE REVIEW

### Construction Project

Construction project is a process where several groups of people work on the development on buildings from concept to

development. The project is divided into several stages where the project actors focus on development according to the roles or responsibilities that have been determined.

According to (Chan, A.P.C. and Chan, A.P.L., 2004), construction projects have many often conflicting objectives that must be met in order for a project to be considered a success. Project goals are dynamic, and success means different things to people at different points in the project life cycle.

### Risk Management

According to (Djohanputro, B., 2008) risk management is a structured and systematic process in identifying, measuring, mapping, developing alternative risk management, and monitoring and controlling risk management. Risk management is the art and science of anticipating and planning for future uncertain events. It is concerned with identifying and analyzing a range of possible outcomes, then control and mitigate their negative impacts. The objective is to understand, and mitigate or control risks (Sakthiniveditha, V., 2015).

### Risk Assessment

Table 1. Probability Scale (AS/NZS 4360 : Risk Management, 2004)

| Level | Occurrence     | Description                       |
|-------|----------------|-----------------------------------|
| 1     | Very Unlikely  | Almost never happen               |
| 2     | Unlikely       | Possible, but rare                |
| 3     | Possible       | Can occur under certain condition |
| 4     | Likely         | Can happen periodically           |
| 5     | Almost Certain | Can happen anytime                |

**Table 2. Severity Scale (Anitasari & Wessiani, 2011)**

| Level | Impact        | Description   |
|-------|---------------|---|
| 1     | Insignificant | Low financial loss  |
| 2     | Minor         | First aid treatment, medium financial loss                              |
| 3     | Moderate      | Medical treatment required, high financial loss                         |
| 4     | Mayor         | Extensive injuries, loss of production capability, major financial loss |
| 5     | Catastrophic  | Death, huge financial loss  |

**Table 3. Risk Assessment Matrix (AS/NZS 4360 : Risk Management, 2004)**

| Probability        | Consequences      |           |              |           |                  |
|--------------------|-------------------|-----------|--------------|-----------|------------------|
|                    | 1 (Insignificant) | 2 (Minor) | 3 (Moderate) | 4 (Mayor) | 5 (Catastrophic) |
| 1 (Very Unlikely)  | LOW               | LOW       | LOW          | LOW       | MEDIUM           |
| 2 (Unlikely)       | LOW               | LOW       | MEDIUM       | MEDIUM    | MEDIUM           |
| 3 (Possible)       | LOW               | MEDIUM    | MEDIUM       | MEDIUM    | HIGH             |
| 4 (Likely)         | MEDIUM            | MEDIUM    | MEDIUM       | HIGH      | HIGH             |
| 5 (Almost Certain) | MEDIUM            | MEDIUM    | HIGH         | HIGH      | HIGH             |

### Cause and Effect Analysis

Cause and Effect Analysis is a structured method to identify the possible risk of complex problems that present several interrelated causes (Lorenada, E.M., 2017). This method classifies the causes of a risk into categories to facilitate identification. This cause information is shown in a fishbone diagram or an Ishikawa diagram. For building a fishbone chart we use arrows or branches: (1) primary branch: represents the effect, (2) major branch: corresponds to the major cause, (3) minor branch: corresponds to the causative and more detailed factors.

### MATERIALS & METHODS

The research is focus on the risks posed by lack of knowledge or not applying risk management at the planning stage. The purpose of this research is to find the most

potential risks that occur in the planning stage of a construction project, especially in the Industrial Building Project.

The risk is evaluated by professional practitioners who have experience in construction projects. The evaluation includes the expected probability of the event and its impact on changes in the scope of work. This study considers each risk among owners, consultants, contractors and others. The data collected is analyzed qualitatively and quantitatively to assess the severity and impact of the event.

The potential risks were identified by the authors based on the available published researches and the interview carried out with experts. The risks were categorized from the Risk Breakdown Structure (PMBOK 6th Edition, 2017) in four major groups, including:

**Table 4. Risk Factor in Industrial Project**

| Main Factor                  | Categories     | Variable | Sub Factor  | Reference               |
|------------------------------|----------------|----------|---|-------------------------|
| Technical Risk (X1)          | Process        | X1.1     | Site Investigation  | Sutoyo (2000)           |
|                              |                | X1.2     | Completeness data of the site conditions                          | Muhharam Noor (2006)    |
|                              |                | X1.3     | Completeness of data to make DED (Detail Engineering Design)      | Document reviews        |
|                              | Design         | X1.4     | Error in design   | Candra Y. (2017)        |
|                              |                | X1.5     | Completeness of DED   | CII (1997)              |
|                              | Technology     | X1.6     | Error due to software used  | Hosen (2006)            |
| Project Management Risk (X2) | Scheduling     | X2.1     | Limited time to prepare for tender                                | Ogulana (2003)          |
|                              | Estimate       | X2.2     | Material specification that are less detailed and less accurate   | Soeharto (1997)         |
|                              |                | X2.3     | BOQ calculation that is not accurate                              | Wideman (1992)          |
|                              | Planning       | X2.4     | Inconsistency between construction plans and field implementation | Ali K. (2017)           |
|                              | Communication  | X2.5     | Lack of coordination between engineering team                     | G. B. Oberlander (1993) |
|                              |                | X2.6     | Lack of coordination between design team                          | Vichian                 |
|                              |                | X2.7     | Lack of coordination between several disciplines                  | Karim El-Dash (2006)    |
|                              |                | X2.8     | Communication between Owner and the design team                   | Muhammad Saqib (2008)   |
|                              | Resources      | X2.9     | Lack of Estimator's experience                                    | Callahan MT (1992)      |
|                              |                | X2.10    | Lack of designer's experience                                     | Wideman (1992)          |
|                              |                | X2.11    | Lack of Engineer's experience                                     | Ogulana (2003)          |
|                              |                | X2.12    | There are no consultants for special disciplines                  | Karim El-Dash (2006)    |
|                              | Prioritization | X2.13    | No quality control system   | Karim El-Dash (2006)    |

**Table 4 Continued...**

|                      |                   |      |  |                       |
|----------------------|-------------------|------|--|-----------------------|
| Commercial Risk (X3) | Subcontractors    | X3.1 | Contractor's experience  | C. K Ho (2001)        |
|                      | Suppliers         | X3.2 | Machine vendor/ supplier change  | Document reviews      |
|                      |                   | X3.3 | Change in the shape, size, location of the machine                               | Document reviews      |
|                      | Client/ Customers | X3.4 | Design changes by Owner (addition / subtraction)                                 | Karim El-Dash (2006)  |
|                      |                   | X3.5 | Owner doesn't fully explain his needs  | Anik R. (2018)        |
| External Risk (X4)   | Regulatory        | X4.1 | Inflation and price fluctuations that cause cost overruns from the original plan | Yu Sun (2008)         |
|                      |                   | X4.2 | Industry standard compliance   | CII (1997)            |
|                      |                   | X4.3 | Change in the government's political and economic situation or policies          | Muhammad Saqib (2008) |
|                      | Market            | X4.4 |  | Anik R. (2008)        |
|                      |                   | X4.5 | Increase in labor costs, material price and equipment price                      | Gusti A.(2015)        |
| Cost Factor (Y)      | Cost Efficiency   | Y1   | Application of Value Engineering   | Karim El-Dash (2006)  |
|                      |                   | Y2   | Application of Lean Construction   | Document reviews      |

The table above is a list of risk factor that will be tested for expert validity and carried out a pilot survey before a questionnaire is made and distributed to respondents.

**RESULT**

From the results of statistical analysis, a finding will be obtained in this study. In the research process, standards were achieved based on secondary data analysis which was translated into research variables will be the basis and reference for obtaining results from primary data (questionnaire) so that the objectives of the research can be achieved. Data processing for the results of the questionnaire survey was analyzed using SPSS version 25 software.

**Statistical Analysis**

**Validity and Reliability Test**

The r-table value with a significance level used 5% obtained r-table Product Moment  $df = 31-2 = 0.355$ . The validity test results of the factors causing change orders on time and cost performance show valid variables because of the value of r-table  $> 0.355$ .

The reliability test in this study uses the internal reliability coefficient of alpha, the questionnaire questions can be said to be

reliable if the Cronbach's Alpha coefficient is above 0,6. The results of the reliability test can be seen in the table below:

**Table 5. SPSS reliability test Case Processing Summary**

| Case Processing Summary |                       |    |       |
|-------------------------|-----------------------|----|-------|
|                         |                       | N  | %     |
| Cases                   | Valid                 | 35 | 100,0 |
|                         | Excluded <sup>a</sup> | 0  | ,0    |
|                         | Total                 | 35 | 100,0 |

a. Listwise deletion based on all variables in the procedure.

(Source. Analysis Results, 2021)

**Table 6. SPSS reliability test Reliability Statistics**

| Reliability Statistics |            |
|------------------------|------------|
| Cronbach's Alpha       | N of Items |
| .918                   | 31         |

(Source. Analysis Results, 2021)

Reliability testing was processed using the Statistical Package for Social Science (SPSS) software. The results of the reliability test on the risk factors are 0.918, as in table 3. Therefore,  $0.903 > 0.60$  so that the questionnaire instrument is valid.

**Multinomial Logistic Regression Test**

The multinomial logistic regression test is a regression model used to solve regression cases with the dependent variable in the form of multinomial with one or more independent variables.

Indicator:

|                                  |
|----------------------------------|
| $P\text{-value} < \alpha (0,05)$ |
|----------------------------------|

(Source. Analysis Results, 2021)

**CASE STUDY**  
**Pareto Analysis**

At this stage, the work items are classified into similar work items and then sort them from the highest cost to the lowest

cost in order to facilitate the research and a pareto distribution graph is made, by determining 80% of the total additional work as the root of the next analysis.

**Table 12. Change in scope of work**

| No.          | Work Item                 | Total Price           | Percentage  | Cumulative (%) |
|--------------|---------------------------|-----------------------|-------------|----------------|
| 1.           | Creamer Tower             | 4.104.280.809         | 27,14%      | 27,14%         |
| 2.           | Operational               | 2.386.881.362         | 15,78%      | 42,92%         |
| 3.           | WTP, Carbon Tank & GWT    | 1.644.610.901         | 10,87%      | 53,79%         |
| 4.           | WWTP                      | 1.367.572.304         | 9,04%       | 62,83%         |
| 5.           | Instant Tower             | 1.047.279.681         | 6,92%       | 69,75%         |

| <b>Total</b> |                           | <b>11.834.982.070</b> | <b>100%</b> |                |

From the table above, the Pareto Diagram has been carry out:

**Fig. 2 Pareto Diagram**

From the table above, 7 work items are selected that have significant influence on change scope of work, which will then be used in the analysis using a Cause and Effect diagram.

**Cause and Effect Analysis Method**

The following is a Cause and Effect diagram from a case study that has been carried out based on Pareto diagram. It can be seen that the main events greatly affect changes in the scope of work. Therefore, the Cause and Effect diagram is used to determine the cause of the event.

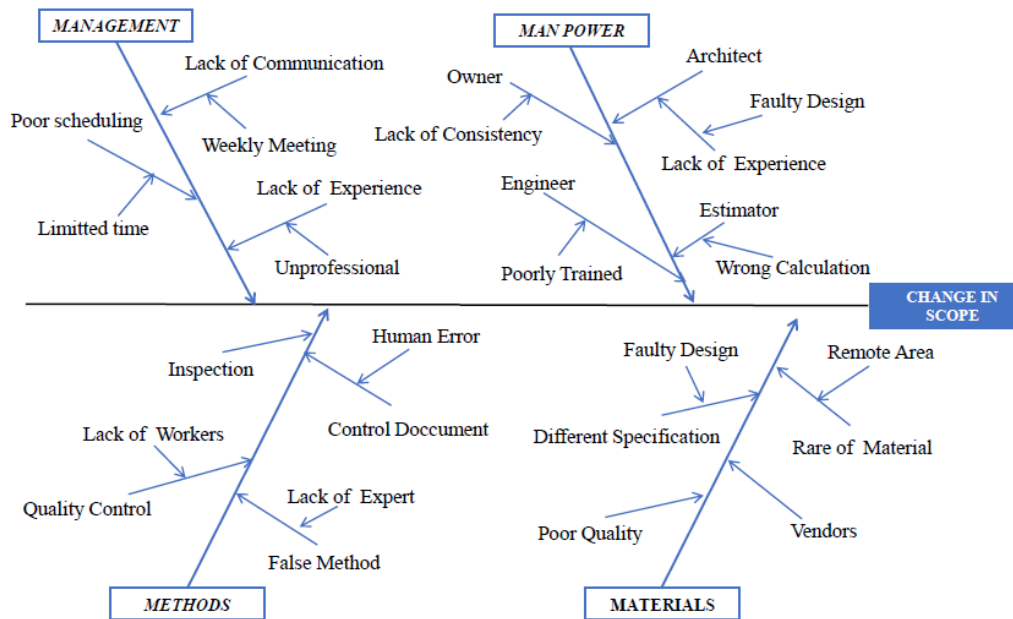

Fig. 3 Cause and Effect Diagram

From the Cause and Effect diagram above, it can be seen that the causes are risk factors that greatly affected in the change scopes of work. These risk factors become the dominant factors which will later be given preventive measures.

**DISCUSSION**

**Risk Register**

Table 12. Risk register

| Risk Level | Rank | Variable                     | Risk Factor  | Risk Response                     |
|------------|------|------------------------------|--|-----------------------------------|
| High       | 1    | X3.4                         | Design changes by Owner (addition / subtraction)                                 | Risk Avoidance                    |

## Risk Response

From the results of the research using questionnaires and case study, it is found that several factors are very influential in the change in scope of work in

Industrial Building Project. And preventive measure should be taken for the dominant risk factor. The following is a table of dominant risk factor and how to prevent it.

**Table 13. Dominant Risk Factor and Risk Response**

| Variable | Dominant Risk Factor  | Risk Response  |
|----------|---|--|
| X3.4     | Design changes by Owner (addition / subtraction)                  | At the time of planning, the project manager should make a list of what needs are needed by the Owner to minimize the design change.   |
| X3.3     | Change in the shape, size, location of the machine                | Ensure the specifications of the machine used are in accordance to the need<br>Conducting survey regarding the need of related machine |
| X1.2     | Completeness data of the site conditions                          | Conduct a site as detailed as possible<br>Remeasure the site   |
| X3.2     | Machine vendor/ supplier change                                   | Ensure a trusted and familiar machine vendor or supplier   |
| X2.5     | Inconsistency between construction plans and field implementation | Conduct weekly meeting to minimize change in the design<br>Design team should be someone who experienced in similar project            |
| X1.5     | Completeness of DED (Detail Engineering Design)                   | Make a list of DED to check after the drawings are complete  |
| X1.4     | Error in design   | Implement a quality control system in each team  |
| X1.1     | Site Investigation  | Site survey must be carried out by the design team so that they can be more accurate in making Detail Engineering Design               |
| X2.1     | Completeness of data to make DED (Detail Engineering Design)      | Ensure that all documents needed for planning are complete<br>Completing the missing data  |
| X1.3     | Limited time to prepare for tender                                | Tender should not be prepared in a short time<br>Recruit more people in the planning team  |
| X2.14    | No quality control system   | Make a quality control team<br>Require the Project Manager to carry out inspections  |

## CONCLUSION

Based on the results of research and processing of secondary data, the conclusions can be drawn as follows:

1. From the results of the statistical tests, it is known that the most significant factors that affect change in scope of work in Industrial Building project are: (X2) project management risk factors and (X1) technical risk factors.
2. From the results of the risk assessment obtained 11 risk factors that have a high risk in influencing the change in scope of work in Industrial Building project, namely: (X3.4) Design changes by Owner, (X3.3) Change in the shape, size, location of the machine, (X1.2) Completeness data of the site conditions, (X3.2) Machine vendor/ supplier change, (X2.5) Inconsistency between construction plans and field implementation, (X1.5) Completeness of DED, (X1.4) Error in design, (X1.1) Site Investigation, (X2.1) Completeness of data to make DED, (X1.3) Limited time to prepare for tender, and (X2.14) No quality control system.

From the results of the study, it can be concluded that the planning stage of a construction project, especially Industrial Building Project has very important influence in the change in scope of work. Therefore, risk management should be carried out as early as possible, namely at the planning stage.
